

Dear authors,

Being an author as well, I fully understand your reluctance to conduct additional experiments, but my advice did not come out of nowhere. I believe that additional chemical data is really needed, because I think that you don't have pure phases. Below are some screens from your Figures:

You can see here that "fluctuations" are of the same intensity as, for instance, 222 reflection has. It means that there might be some impurity. May be which came from initial reagents. But it can also affect the spinel structure. Of course, maybe not. That's why additional analyzes are needed.

As I said, I understand your position, but I can't recommend the paper for publication without these data.
